Title: *Effect of Interlayer Coupling and Biasing on Spin Transfer Torque Switching in Ferromagnetic Nanopillars*

Supervisor: Prof. M. Daniel

Description: Spin transfer torque induced magnetization switching has recently attracted much interest due to its potential applications in magnetic random access memory (MRAM), fast programmable logic, high-density magnetic storage devices, magnetic sensors and in high frequency devices for telecommunications. Magnetic storage devices and magnetic sensors based on Giant Magnetoresistance (GMR) and Tunnelling Magnetoresistance (TMR) effects require high quality multilayers constructed out of ultrathin ferromagnetic and non-magnetic films. The performance of these devices strongly depend on the morphological and structural properties of the films and their physical characteristics. Among them, the crucial factor is the interlayer coupling between the two ferromagnetic layers separated by a non-magnetic spacer. Various interlayer coupling

mechanisms have been reported. Among them, pinhole coupling, orange peel coupling, biquadratic coupling and RKKY coupling are important ones. These interlayer couplings play an important role in the understanding of magnetization switching mechanism and GMR of spin valves and TMR of magnetic tunnel junction structures. We have done a systematic and in-depth study about the effect of interlayer coupling that arises due to the interface roughness namely orange peel coupling and biquadratic coupling on spin transfer torque magnetization switching in trilayer and pentalayer nanopillar structures. Further, we have investigated the effect of biasing on spin transfer torque magnetization switching in the pentalayer structure, in order to reduce the switching time and critical current density required to initiate the magnetization switching. The magnetization switching dynamics of the free layer magnetization in nanopillar are basically nonlinear in nature and is governed by the Landau-Lifshitz-Gilbert-Slonczewski (LLGS) equation which is a highly nontrivial vector nonlinear evolution equation. By solving this LLGS equation, we can understand the underlying magnetization dynamics. For time-independent case, LLGS equation is analytically solved and the critical current density required to switch the magnetization is calculated. Then the full LLGS equation is solved numerically by using Runge-Kutta fourth order procedure for each case and from the numerical simulations study we understood the effect of interlayer coupling and biasing on spin transfer torque switching. Our important findings are both orange peel coupling and biquadratic coupling reduces the switching time. Even though biquadratic coupling reduces the switching time, the lowest switching time is obtained through orange peel coupling. Further, we found that biasing the ferromagnetic layers of the nanopillars reduces the switching time considerably. Although biasing in the case of pinned layer enhances the spin transfer torque acting on the free layer and reduces the switching time, the fastest magnetization switching is achieved in the case of free layer biasing configuration.
